Over the past year, we have offered an independent analysis of the dairy margin protection programs put forth and passed by the U.S. House of Representatives and the U.S. Senate. This research demonstrated that a safety net program encompassing both the milk price and the feed price in the form of an income-over-feed-cost margin would succeed in providing needed financial relief to dairy farmers during times of low milk production margins. We also identified and discussed three significant issues: adverse gaming, functional equity of dairy market stabilization and the distribution of program benefits.

Since then, the Agricultural Act of 2014 was passed by both houses of Congress and signed into law by President Obama on February 7, 2014. In this article, we review the margin protection provisions in the new law and examine to what extent adverse gaming incentives and distributional effects may still exist. In addressing these issues, we will demonstrate that the distribution of program benefits no longer follows closely the distribution of milk production and is more aligned with the benefit distribution of the Milk Income Loss Contract (MILC) program. We will also explain that adverse gaming incentives still exist, and in the absence of formal rate-making procedures, can be significantly reduced by instituting a gap between the sign-up date and the beginning of the coverage period.

**What is the Margin Protection Program for Dairy Producers?**

The dairy title of the Agricultural Act of 2014 would repeal a number of existing dairy safety net programs and replace them with two new programs: Margin Protection Program for Dairy Producers and a Dairy Product Donation Program. Both programs will become effective by September 1, 2014. Most notably of which, and the focus of this post, is the margin protection program to replace MILC. The margin protection program is a voluntary program which pays indemnities when the average difference between the USDA national All-Milk price and a ration index reflecting the national cost of feeding dairy animals falls below a user-selected coverage level.

Over the 2000-2013 years, the dairy production margin has ranged from a low of $2.15 to a high of $14.63 and averaged $8.26 per hundredweight (cwt). Margin protection is available from $4 to $8 per cwt in $0.50 increments and offers protection on up to 97 percent of the historical average margin. Enrolled producers may receive coverage on 25 to 90 percent of their milk production history.

The production history is to be determined at sign-up in the first year of the program and is defined as the highest level of annual milk production during the 2011, 2012 or 2013 calendar years. In subsequent years, a farm’s production history will be updated by the USDA to reflect only the increase in national average milk production. Individual milk production base growth above the national average will not be reflected in the updated production base.

In order to participate in the margin protection program and receive no-cost $4 coverage, dairy operations must annually pay an administrative fee of $100. Additional margin protection (strike price) on levels above $4 per cwt can be selected by a participating dairy at supplementary costs with premium rates depending on a farm’s production history. Premiums range from $0.01 for $4.50 coverage to as high as $1.36 for $8 coverage. The premium schedule is fixed for the life of the farm bill, but premium discounts of 25 percent are specified for the 2014 and 2015 calendar years for all but the $8 level.
Revisiting the distribution of expected benefits

Contrary to the existing MILC safety net program for dairy producers, the margin protection program does not include adjusted gross income limitations or fixed caps on production and therefore on the magnitude of potential benefits. In the final compromise, the margin protection program was modified to be more accommodating to small and medium-sized dairies by reducing the premium rates by as much as 50 percent for the first four million pounds of production history. Finally, the premium rates for production history in excess of four million pounds were increased by $0.20 to $0.30 for the $7 to $8 coverage options. Using average milk production of 21,806 pounds per cow per year, the four million pound cap represents a 183-cow dairy, and just shy of 85 percent of U.S. dairies are below this threshold.

To evaluate the distribution of margin protection benefits following these premium adjustments, using data on milk production provided by the USDA, we compared simulation results of MILC, Dairy Freedom Act, Dairy Security Act and the Agricultural Act of 2014. (Figure 1) Under MILC, we estimated that dairies with less than 100 cows (approximately 70 percent of farms) account for about 39 percent of net expected benefits and dairies with more than 1,000 cows (3 percent of farms) account for 9 percent of net expected benefits.

Under the Dairy Freedom and Security Acts, we projected that farms with more than 1,000 cows would account for 36 percent of benefits during low margin outcomes. Now, under the margin protection program in the Agricultural Act of 2014, we find that the distribution of net expected benefits closely aligns with those simulated under MILC. Farms with fewer than 100 cows would continue to receive approximately 38 percent of the expected benefits, and farms with more than 1,000 cows would account for approximately 15 percent of benefits during low margin outcomes. For larger dairies, this allocation represents an improvement over MILC considering that not only does the relative proportion of benefits increase (9 percent to 15 percent) but at the same time total outlays are also anticipated to be higher than MILC given the lack of payment limitations or hard eligibility constraints.

Through the altered premium structure, and given 2013 expected margins, the distribution of expected benefits no longer mirror the distribution of milk production and instead provide more coverage on a per-cwt basis to smaller dairy operations. For example, during the simulated 2013 margins, the average net payment for farms below 100 cows was $0.80 per cwt under $7.50 coverage. Meanwhile, for the herds with 1,000-plus head, the average net payment was only $0.14 per cwt under $6.50 coverage. The difference in per-cwt net payments is due to the higher premiums rates applied to the largest dairy operations. Thus, by design, the per-cwt benefits are higher for small producers by means of the premium reductions and discounts but also due to higher premium rates, effectively deterring participation at higher coverage levels for the largest dairy operations.

Only when the margin coverage levels of $7 and above are expected to be deeply “in the money” would a larger producer find it financially beneficial to purchase such protection. Under such a scenario, when margins are catastrophically low, as was the case in 2009, and using data provided by the USDA, we found indemnities with $8 coverage could exceed $6 million dollars per farm for some of the nation’s largest dairymen. When factoring in participation costs, net payments were over $3 million dollars for some of the larger dairies in the simulation.

Additionally over 10 percent of the 1,072 dairies in the 1,000-plus head category had net payments above $1 million dollars given the 2009 margin simulation. Thus, we conclude that only when higher coverage levels are deep in the money will payments per cwt be more consistent across participating farm sizes and result in the distribution of net benefits following closely to the distribution of milk production.

Does adverse gaming still exist?

The concept of the margin protection coverage levels being “in the money” or “out of the money” relates to the intrinsic value of the margin coverage level and borrows from the idea that upon the sign-up date the margin protection level, or strike price, which ranges from $4 to $8 per cwt, may be above (in the money), equal to (at the money) or below (out of the money) the expected margin forecast using CME futures and options prices. Coverage levels can be categorized into one of the three categories during each sign-up or registration period because while the premium rates and coverage levels remain fixed, milk and feed markets are constantly updating to reflect new information on prices and expected volatility. When margin coverage is in the money it has intrinsic value, and during the annual sign-up process dairy farmers can strategically select the coverage level that has the highest intrinsic value or expected financial returns.

As an example, consider in Figure 2, page 56, the expected production margins at the beginning of 2009, the beginning of 2014 and in October 2008 for the 2009 calendar year. Beginning-of-the-year 2009, expected margins were deeply in the money such that $8 coverage had the highest average intrinsic value of $2.85 per cwt. As a result, the expected benefits of participation would have warranted coverage as high as $8 per cwt for the largest dairy operations – despite paying premiums as high as $1.36 per cwt.

Alternatively, given favorable 2013 crop production and robust demand for dairy products, expected margins for 2014 indicate a very low probability of indemnity payments and are categorized as out of the money. Aside from opting completely out of the program, dairy farmers can strategically select the coverage level that has the highest intrinsic value or expected financial returns.

program, the lowest coverage level of $4 would have zero intrinsic value and would provide the greatest expected net benefits because it carries only the administrative fee of $100. As demonstrated, the modifications to the premium structure alter, but do not eliminate, the financial incentives to strategically select margin protection coverage based on the anticipated risk environment and money-ness. Adverse gaming incentives still exist; however, a proposal put forth by Marin Bozic and us could further reduce the adverse gaming potential by instituting a gap between the sign-up date and the beginning of the coverage period. We propose that by instituting a six-month gap between a sign-up date and the beginning of the coverage period, the ability to forecast margins over the coverage period is substantially reduced. While a six-month gap may not be politically feasible, a 60-day or 90-day gap may be acceptable given that the term structure of income over feed cost margins exhibit mean-reverting behavior. The effect of a 90-day gap on the intrinsic value and money-ness is demonstrated in the third panel of Figure 2. In this example, a 90-day gap between the sign-up and coverage start date carries no intrinsic value at $8 and is closer to at the money, thereby reducing the potential for strategically timed positive expected benefits of margin protection.

When margin protection coverage is closer to at the money, the adverse gaming incentives are reduced as future indemnities are less certain. As a result, the decision to participate in the program, and at what coverage level, would be made based on a farm’s appetite for risk and not on the ability to strategically game the program to one’s financial advantage.

Summary

The new dairy farm safety net program places an emphasis on protecting farm income over feed costs margins. By focusing on margins, and not milk price or countercyclical revenue support, dairy producers across the U.S. regardless of location and management style are better protected against severe downturns in the milk price, rising livestock feed prices or a combination of both.

In this article, we’ve demonstrated that except during times when margin coverage is deep in the money, the distribution of program benefits will follow closely the distribution of benefits under the previous MILC program while simultaneously providing additional income support for the nation’s largest dairy operations. We also show that adverse gaming incentives still exist with the Dairy Margin Protection Program but can be mitigated by specifying an earlier sign-up date for coverage decisions, specifically we propose 60 or 90 days.

With the Agricultural Act of 2014 becoming law, the secretary of agriculture is provided the authority to define many of the rules by which the dairy programs will operate.
